Dynamic Programming

Dis (USTC) Introduction to

The most common problem being solved is the 0-1 knapsack problem, which restricts the number  $x_i$  of copies of each kind of item to zero or one. Given a set of n items numbered from 1 up to n, each with a weight  $w_i$  and a value  $v_i$ , along with a maximum weight capacity W,

$$\max \sum_{i=1}^n v_i x_i$$
 s.t.  $\sum_{i=1}^n w_i x_i \leq W$  and  $x_i \in \{0,1\}$ .

- 4 ロ ト 4 個 ト 4 恵 ト 4 恵 ト 9 Q C C

Assume  $w_1, w_2, \ldots, w_n, W$  are strictly positive integers. Define m[i, w] to be the maximum value that can be attained with weight less than or equal to w using items up to i. We can define m[i, w] recursively as follows:

```
m[0, w] = 0
```

$$m[i, w] = m[i-1, w] if w_i > w$$

$$m[i, w] = \max(m[i-1, w], m[i-1, w-w_i] + v_i) \text{ if } w_i \leq w.$$

Dis (USTC)

Assume  $w_1, w_2, \ldots, w_n, W$  are strictly positive integers. Define m[i, w] to be the maximum value that can be attained with weight less than or equal to w using items up to i. We can define m[i, w] recursively as follows:

$$m[0, w] = 0$$

$$m[i, w] = m[i-1, w] if w_i > w$$

$$m[i, w] = \max(m[i-1, w], m[i-1, w-w_i] + v_i) \text{ if } w_i \leq w.$$

Dis (USTC)

Introduction to

The solution can then be found by calculating m[n,W]. To do this efficiently, we can use a table to store previous computations. This solution will therefore run in O(nW) time and O(nW) space.

Weight Limit (i):	0	1	2	3	4	5	6	7	8	9	10	11
$w_1 = 1 \ v_1 = 1$	0	1	1	1	1	1	1	1	1	1	1	1
$W_2 = 2 V_2 = 6$	0	1	6	7	7	7	7	7	7	7	7	7
$W_3 = 5 V_3 = 18$	0	1	6	7	7	18	19	24	25	25	25	25
$W_4 = 6 V_4 = 22$	0	1	6	7	7	18	22	24	28	29	29	40
$W_5 = 7 V_5 = 28$	0											

## Optimal substructure

Fibonacci sequence

$$fib(n) = fib(n-1) + fib(n-2)$$

Dijkstra's algorithm for the shortest path problem

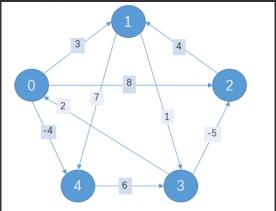

$$d[y] = \min_{x} \{d[y], d[x] + w(x, y)\}$$

How to define the status and stage of problems is essential.

- ( ㅁ ) ( 🗇 ) ( 호 ) ( 호 ) ( 호 ) ( 호 )

Dis (USTC) Introduction

Given a directed graph (V,A) with source node s, target node t, and cost  $w_{ij}$  for each edge (i,j) in A, consider the program with variables  $x_{ij}$ .

Integer programming formulation:

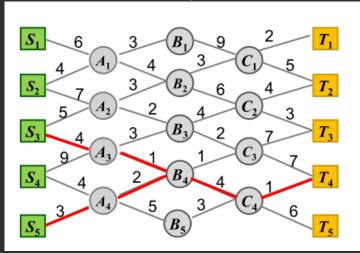

$$\min \sum_{(i,j)\in A} w_{ij} x_{ij}$$

s.t. 
$$\sum_{j} x_{ij} - \sum_{j} x_{ji} = \begin{cases} 1, & \text{if } i = s; \\ -1, & \text{if } i = t; \\ 0, & \text{otherwise.} \end{cases}$$

 $x \in \{0,1\}$  and for all i.

- ( ロ ) ( 레 ) ( E ) ( E ) ( O )

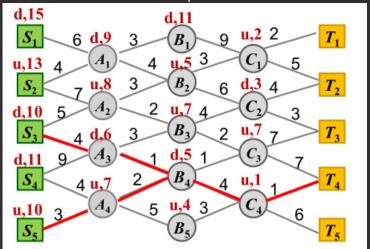

Find the shortest path from s to t.

Stage1 
$$F(C_l) = \min_m \{C_l T_m\}$$
  
Stage2  $F(B_k) = \min_l \{B_k C_l + F(C_l)\}$   
Stage3  $F(A_j) = \min_k \{A_j B_k + F(B_k)\}$   
Stage4  $F(S_i) = \min_j \{S_i A_j + F(A_j)\}$ 

- 《ㅁㅏ《畵ㅏ 《돌ㅏ 《돌ㅏ 》 돌 : 씨९은

Find the shortest path from s to t.

Integer & Linear Programming

# Integer Programming

Shortest path problem

$$\begin{aligned} &\min \sum_{(i,j) \in A} w_{ij} x_{ij} \\ &\text{s.t.} \sum_{j} x_{ij} - \sum_{j} x_{ji} = \begin{cases} 1, & \text{if } i = s; \\ -1, & \text{if } i = t; \\ 0, & \text{otherwise.} \end{cases} \\ &x \in \{0,1\} \text{ and for all } i. \end{aligned}$$

## Totally Unimodular Matrix

- Every entry in A is 0, +1, or -1;
- Every column of A contains at most two non-zero (i.e., +1 or -1) entries;
- If two non-zero entries in a column of A have the same sign, then the row of one is in B, and the other in C;
- If two non-zero entries in a column of A have opposite signs, then the rows of both are in B, or both in C.

4 □ ▷ ◀률 ▷ ◀ 불 ▷ ◀ ⑤

#### TU Matrix

- Totally unimodular matrices are extremely important in polyhedral combinatorics and combinatorial optimization since they give a quick way to verify that a linear program is integral (has an integral optimum, when any optimum exists).
- Specifically, if A is TU and b is integral, then linear programs of forms like  $\{\min cx \mid Ax \geq b, x \geq 0\}$  or  $\{\max cx \mid Ax \leq b\}$  have integral optima, for any c. Hence if A is totally unimodular and b is integral, every extreme point of the feasible region (e.g.  $\{x \mid Ax \geq b\}$ ) is integral and thus the feasible region is an integral polyhedron.

### Another Perspective

Recall the simplex method for linear programming.

$$Bx = b$$
$$x^* = (B^{-1}b, 0)$$

How to obtain the inverse of B?

Cramer's rule:

$$B^{-1} = B^*/\mathsf{det}(B)$$

Dis (USTC)

## Simplex Method

- Feasible region(Convex polytope)
- Basic feasible solution(Extreme point)
- Basic variables(Identity matrix)
- Entering variable selection
- Leaving variable selection
- Pivot operation
- Reduced costs

### Another Perspective

The simplex method is an iteration process.

$$x' = x\theta\lambda$$

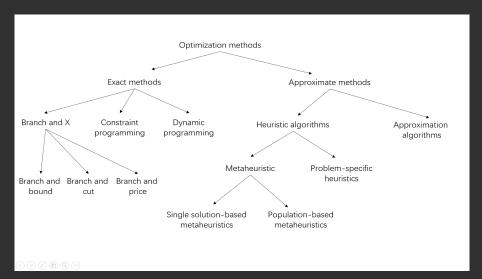

How to obtain the inverse of B?

Cramer's rule:

$$B^{-1} = B^*/\det(B)$$

# Cutting Plane Method

Cutting Planes

# Gomory's Cut

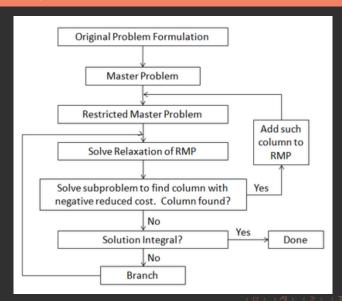

- Using the simplex method:  $x_i + \sum \bar{a}_{i,j} x_j = \bar{b}_i$  where  $x_i$  are the basic variables and the  $x_j$ 's are the nonbasic variables.
- Rewrite this equation: integer parts(left) and the fractional parts(right):

$$x_i + \sum \lfloor \bar{a}_{i,j} \rfloor x_j - \lfloor \bar{b}_i \rfloor = \bar{b}_i - \lfloor \bar{b}_i \rfloor - \sum (\bar{a}_{i,j} - \lfloor \bar{a}_{i,j} \rfloor) x_j.$$

- Right side is less than 1 and the left side is an integer, therefore the inequality:  $b_i \lfloor b_i \rfloor \sum (\bar{a}_{i,j} \lfloor \bar{a}_{i,j} \rfloor) w_j \le 0$  must hold for any integer point in the feasible region.
- $\blacksquare$  The inequality above is a cut with the desired properties. Introducing a new slack variable  $x_k$  for this inequality, a new constraint is added to the linear program, namely

$$x_k + \sum (\lfloor \bar{a}_{i,j} \rfloor - \bar{a}_{i,j}) x_j = \lfloor \bar{b}_i \rfloor - \bar{b}_i, \ x_k \geq 0, \ x_k$$
 an integer

#### Summary

Finally, we should master how to settle a problem in that way, so that we will have more ideas and try different methods.

In the process of practice, they can guarantee to find the global solution, but in solving some typical practical problems, the price is too high, or it is easy to fall into local optimum. Because it's hard to accelerate the algorithm that can guarantee to find the optimal solution, that is, for most practical problems, it is difficult to find polynomial algorithm, because most of them are NP hard problems, then the rest selection is to design an algorithm that can jump out of local optimum.
